PROSPECCION GRAVIMETRICA

1.- INTRODUCCION

1.1.- PRESENTACION

Este informe se refiere a la Prospección gravimétrica - realizada por ENADIMSA para el I.G.M.E. en el Campo de Cartagena, durante el año 1.982.

Su ejecución se enmarca dentro de un conjunto de trabajos de exploración, encaminados a determinar la distribución en profundidad de las estructuras geológicas cartografiadas - en superficie.

1.2.- OBJETIVOS

El programa de prospección gravimétrica se encaminaba a localizar y determinar la situación sobre el terreno de anomalías de gravedad provocadas por estructuras geológicas casi totalmente ocultas por recubrimientos terciarios y cuaternarios y así, en correlación con los demás métodos geofísicos empleados, permitir la óptima implantación de los sondeos mecánicos, en base a los conocimientos geológicos, para el aprovechamiento geotérmico de la cuenca.

1.3.- ZONA INVESTIGADA

La zona objeto de esta investigación, situada en la provincia de Murcia, comprende prácticamente la totalidad del denominado Campo de Cartagena y su prolongación occidental ,

atravesando el valle del Guadalentín hasta la localidad de Totana (Fig. 1).

1.4.- PROGRAMACION

Sobre el mapa topográfico de la zona en estudio se situaron estaciones uniformemente repartidas con una densidad de una por km^2 para completar la investigación gravimétrica que realizó el I.G.M.E. en la zona de Cartagena y poder presentar un mapa conjunto con el resultado de ambas investigaciones.

1.5.- COMPOSICION DEL EQUIPO

Para la realización del trabajo se dispuso del siguiente personal y material:

a) Personal:

- 1 Supervisor
- 1 Jefe de Equipo
- 1 Operador de gravímetro
- 2 Topógrafos
- 1 Calculista
- 6 Peones

b) Material:

- 1 gravímetro Lacoste Romberg
- 1 gravímetro Worden
- 3 Taquímetros Wild T-16
- 1 Taquímetro Wild T-2
- 1 Distanciómetro Wild DI-4L

Fig. 1

PLANO DE SITUACION

2.- TRABAJOS REALIZADOS

2.1.- VERIFICACION DEL GRAVIMETRO

El gravímetro Lacoste-Romberg n° 307 se calibró en Madrid sobre las bases que el IGN tiene situadas en Madrid y el Valle de los Caídos. Las constantes para este gravímetro, en el rango de lecturas obtenidas en la zona, son las siguientes:

| LECTURA | Equivalencia en mgals | Cte. para el exceso |
|---------|-----------------------|---------------------|
| 3300.00 | 3524.75 | 1.07071 |
| 3400.00 | 3631.82 | 1.07092 |
| 3500.00 | 3738.91 | 1.07109 |

Posteriormente y ya sobre la zona de trabajo se eligió la Base gravimétrica n° 7 como punto de control para la comprobación del estado y funcionamiento del gravímetro durante la campaña de medidas.

El gravímetro Worden Prospector n° 813 se calibró en las bases de la Red de Calibración que el IGN tiene instaladas en La Carolina (n° 35) y Guarromán (n° 36) obteniéndose una constante de 0.09080 mgals/división.

2.2.- RED DE BASES

Sobre la zona de trabajo se estableció una red de diez bases repartidas de forma que el tiempo comprendido entre pa sos consecutivos por una base no fuese superior a dos horas.

A continuación se realizó la unión gravimétrica de dichas bases. En la figura n° 2 se indica el esquema de unión y en los planos n° 1 a 3 el valor de los incrementos relati vos de gravedad entre las bases.

Para obtener los valores de gravedad absoluta en las bases, se enlazó la base n° 7 con la Base Nacional del IGN en el Ayuntamiento de Cartagena (Señal NP-1806), y un valor de gravedad $g_0 = 980018,17$ mgals. (SGR 1967).

Los valores de gravedad obtenidos para las bases a par tir de este enlace, así como su situación, coordenadas y fo tografía se adjuntan en las figuras n° 3 a n° 12.

2.3.- MEDIDAS GRAVIMETRICAS Y CONTROL DE CALIDAD

Una vez situadas topográficamente las estaciones sobre el terreno, se midieron con el gravímetro mediante la coloca ción del "plato" con nivel esférico sobre la señal de la es tación, en el caso de las carreteras, o junto a la estaqui lla en el caso de caminos. Una vez nivelado el gravímetro so bre el plato, se tomaba la lectura, iterando la operación - de nivelar y leer.

Para estimar la precisión de las medidas, un 9% de es tas se repitieron en programas diferentes. En la tabla adju nta se indican las diferencias de gravedad obtenidas.

2.4.- CORRECCIONES DE LAS MEDIDAS GRAVIMETRICAS

Las lecturas del gravimetro se corrigieron del efecto lunisolar mediante un programa de ordenador publicado por "Indiana Geological Survey" con apreciación de media centésima de miligal.

Eliminado de las medidas el efecto lunisolar, estas se corrigieron de deriva, repartiendo la diferencia de medidas obtenida en las bases de partida y llegada, linealmente en función del tiempo, entre las estaciones del itinerario.

La gravedad observada g_0 se obtiene por adición algebraica, del incremento resultante entre la base y la estación, al valor de gravedad obtenido para la base mediante el enlace con la Red Nacional.

El cálculo del efecto topográfico "T" se realizó en tres fases. La primera sobre el terreno al efectuar el levantamiento de la estación. Abarcaba de la zona B a la C de la plantilla de Hammer.

La segunda fase se realizó en gabinete sobre mapa de la zona a escala 1/50.000 usando las plantillas de Hammer desde la zona E a la H.

La tercera fase, corrección de las zonas I a M, se realizó por el método de la parábola de Neuman.

Los valores de estas correcciones se calcularon para

densidad de 2 gr/cm^3 , transformándose posteriormente para los valores de densidad media adoptados en la zona.

La corrección de altura (F-B.D) se realizó con un valor del coeficiente de Faye de 0.30854 mgal/m y de Bouguer $- 0.04192.D \text{ mgal/m}$, siendo $D = 2 \text{ gr/cm}^3$.

Para el cálculo de la gravedad normal " g_n " se ha utilizado la fórmula de la gravedad 1967:

$$g_n = 978031.85 (1 + 0.005278895 \text{ sen}^2\psi + 0.000023462 \text{ sen}^4\psi) \text{ mgals}$$

en la que 978031.85 es el valor de la gravedad en el ecuador y " ψ " la latitud del punto.

El cálculo de la gravedad normal para cada punto se hizo mediante ordenador a partir del valor de la latitud de cada estación, deducida de sus coordenadas UTM.

2.5.- CALCULO DE ANOMALIAS DE BOUGUER

La anomalía de Bouguer " A_B " viene definida por la siguiente expresión: si

$$A_B = g_0 - g_n - (F-B.D).Z-T$$

siendo Z la cota absoluta de la estación en metros.

Los valores de anomalía de Bouguer se calcularon mediante un programa de ordenador.

Con los datos de entrada:

- Número de estación

- Coordenadas U.T.M. de la estación en m.
- Cota de la estación en cm.
- Valor de la gravedad media en cmgal.
- Efecto topográfico en cmgal.

Se obtuvieron los siguientes datos de salida:

- Número de hoja topográfica E: 1/50.000
- Número de estación
- Coordenadas U.T.M. (X,Y) en m
- Cota (Z) en m
- Gravedad medida (G) en mgals
- Gravedad normal (GN) en mgals
- Efecto topográfico (T) en mgals
- Anomalía de Bouguer (A) para $D = 2\text{gr/cm}^3$
- Factor de conversión (C)
- Anomalías de Bouguer para densidades 2.3. y 2.4. gr/cm^3
(A_1, A_2) en mgals.

Este listado de salida se adjunta al final del texto.

2.6.- MAPAS DE ANOMALIAS

En el plano n° 4 se refleja la situación y anomalía de Bouguer $d = 2.4$ de las estaciones. Con estos valores se ha realizado el mapa de isolíneas (Plano n° 5). La elección de esta densidad de reducción se apoya en varios factores, pero fundamentalmente por el conocimiento de la columna litológica que constituye la cubierta sedimentaria. Anteriormente, ya el I.G.M.E. había utilizado esta densidad de reducción.

La separación Regional-Residual ($d = 2,4\text{gr/cm}^3$) se realizó por un procedimiento de ajuste polinómico de superficies de diverso grado eligiéndose la de grado tres al ser la que

estadísticamente daba mejor coeficiente ajustado-residuo con relación a los grados de libertad.

2.7.- TOPOGRAFIA

En todas las estaciones se determinó su posición y cota. Las coordenadas de cada punto se obtuvieron en el sistema U.T.M.

Los métodos utilizados para determinar la planimetría y altimetría de las estaciones fueron los de poligonación con radiación de alta precisión mediante distanciometro y poligonación cerrada punto a punto con taquímetro. En el trabajo con distanciometro se establece una poligonal principal desde la cual se radian los puntos necesarios para el levantamiento. Estos puntos de la poligonal, normalmente no son utilizados como estaciones, al estar situados en lugares elevados y de fuerte efecto topográfico en su entorno próximo.

Los poligonales se enlazaron a los vértices que se indican a continuación:

| HOJA 1/50.000 | V E R T I C E | X (UTM) | Y (UTM) |
|------------------------------|--------------------|---------|-----------|
| TORREVIEJA (935) | LA VIEJA | 694.182 | 4.202.765 |

| | ROS | 680.106 | 4.187.466 |
| | RAME | 688.138 | 4.178.067 |
| | F. ALAMO DE MURCIA | 661.370 | 4.176.962 |
| | AULLO | 668.646 | 4.183.490 |
| | LA PALMA | 679.757 | 4.173.460 |

| HOJA 1/50.000 | V E R T I C E | X (UTM) | Y (UTM) |
|-------------------|-------------------------|---------|-----------|
| MURCIA (934) | M O L I N O | 680.652 | 4.195.913 |
| | O R U J A | 665.639 | 4.192.758 |
| | L O S S A N T I A G O S | 671.561 | 4.190.836 |
| SAN JAVIER (956) | S. J A V I E R | 690.727 | 4.186.713 |
| | S A A V E D R A | 690.171 | 4.184.238 |
| T O T A N A (954) | M O R R A | 645.394 | 4.175.223 |
| | R E O L L A | 647.610 | 4.180.252 |
| | CUEVAS DE REYLLO | 654.776 | 4.177.979 |

Al encontrarse fuertes diferencias en los cierres altimétricos de los enlaces a los vértices, ésta se enlazó a las señales de nivelación de alta precisión NAP-J-487 y NAP-J-485 de la carretera Murcia-Cartagena.

La precisión de las coordenadas establecidas es buena en el caso del método taquimétrico y muy buena utilizando el distanciómetro.

PROSPECCION MAGNETOMETRICA

1.- PRESENTACION Y OBJETIVOS

Esta parte del informe se refiere a la investigación - magnetométrica, realizada por ENADIMSA para el I.G.M.E. en el área del Campo de Cartagena, de marzo a mayo de 1.982.

Su ejecución se enmarca dentro de un conjunto de estudios encaminados a determinar la estructura profunda de esta cuenca.

Esta parte de la prospección geofísica se encamina, conjuntamente con las prospecciones gravimétrica y eléctrica, a diferenciar la presencia de rocas volcánicas y el tipo de basamento y demás estructuras resultantes de la aplicación de los diferentes métodos geofísicos empleados, por medio del contraste de susceptibilidad existente entre ellas.

2.- TRABAJOS REALIZADOS

La programación de la campaña y la toma de datos se realizó en paralelo a la campaña de gravimetría de la primera fase.

Se eligieron siete bases, comunes a la prospección gravimétrica, tras numeradas anteriormente como 1, 2, 3, 4, 5, 7 y 9. El esquema de enlace de bases se refleja en el plano n° 6.

Todas las mediciones efectuadas en esta campaña se realizaron con un magnetómetro de saturación Flux-Gate, Scintrex modelo FM-2, de lectura directa.

La duración de los itinerarios se hizo que fuera menor de 1 hora y media, cuidando que las lecturas en base al mediodía coincidieran con la inflexión de variación diurna que experimenta el campo geomagnético.

Se tomaron 500 estaciones, con la misma separación entre ellas que en gravimetría.

En la fig. 13 se representa el cierre de bases magnetométricas.

Fig. 13

ESQUEMA DE CIERRES DE BASES MAGNETOMETRICAS

3.- TRATAMIENTO DE DATOS

Los datos de campo han sido corregidos de deriva instru
mental, variación diurna y fecha común.

Se ha eliminado el efecto de campo geomagnético normal,
que en nuestra zona es del orden de 100 nT por cada 12 km ,
mediante el ajuste de los datos corregidos a una superficie -
polinómica de primer grado.

A partir de los valores residuales de intensidad del
campo situados en planta (plano n° 7), se han trazado isoanó
malas con un intervalo de 10 nT (plano n° 8). La variación má
xima encontrada en la zona es de 190 nT.

INTERPRETACION

1.- BASE GEOLOGICA

En las hojas geológicas existentes de la zona, aparecen numerosos datos y bibliografía para acercarnos al conocimiento de los diferentes materiales que componen el basamento y el relleno de las cuencas que constituyen el denominado Campo de Cartagena.

1.1.- ESTRATIGRAFIA

Vamos a intentar presentar una simplificada estratigrafía, que puede servir de ayuda para la interpretación de los mapas de anomalías obtenidos. La variación espacial de los valores de anomalía de Bouguer será debida, principalmente, al contraste de densidad existente entre el basamento, metamórfico Paleozoico, Bético "sensu stricto", y la cobertera sedimentaria Terciario-Cuaternaria. El contraste de susceptibilidad entre los esquistos y neises del Nevado-Filábride, las rocas básicas Paleozoico-Terciarias y la cobertera sedimentaria, serán el origen de las anomalías magnéticas.

De muro a techo (Zona Central-Septentrional):

BASAMENTO: Bético

- Complejo Nevado-Filábride, esquistos y neises en la base y mármoles a techo. Estos últimos con una potencia de hasta 300 m.

- Complejo Alpujárride (incluido Ballabona-Cucharón) - Filitas en la base y unos 300 m de Dolomías y Calizas a techo.

COBERTERA: Terciario-Cuaternaria.

- Conglomerados de base, Helveciense-Tortoniense.
- 500 a 1000 m de margas con intercalaciones de areniscas y 100 a 500 m de Conglomerados con Calcarenitas al techo. Tortoniense superior.
- 500 a 1000 m de margas, con intercalaciones de areniscas y yesos al techo. Andaluciense.
- 40 a 80 m de Calizas (Calizas de Benejuzar) entre dos paquetes de margas y a techo 20 a 40 m de Areniscas, denominadas de Bigastro. Plioceno.
- Serie arcillosa, cuaternaria, con intercalaciones de caliche.

1.2.- TECTONICA

Los rasgos fundamentales que caracterizan la zona son: la acumulación de diferentes materiales, producida por las sucesivas superposiciones de mantos de corrimiento; los diferentes sistemas de fracturas que rompen la continuidad de las estructuras, tanto de Este a Oeste como de Norte a Sur; la cobertera neogeno-cuaternaria, que se apoya directamente sobre las unidades béticas S.S., regida estructuralmente por continuos movimientos del substrato.

Estructuralmente, aparecen dos directrices en la zona: la Bética WSW-ENE y otra perpendicular NW-SE.

2.- ANALISIS DEL MAPA DE BOUGUER -
Y DEL MAPA RESIDUAL MAGNETICO.

Están perfectamente definidos, como ya era evidente en el anterior estudio del IGME, los umbrales de Fuente Alamo y Cabezo Gordo y la cuenca de Torre Pacheco.

Casi la totalidad de la zona investigada presenta fuertes gradientes de anomalía de Bouguer, como reflejo de la importancia del juego estructural del basamento.

La depresión gravimétrica de San Pedro del Pinatar - Pilar de La Horadada y la depresión del valle del Guadalentín presentan unas características diferentes del resto de la zona. La primera por la disminución del gradiente general como si cambiara el estilo tectónico del zócalo y la segunda por la gran compartimentación que sugiere el mapa de Bouguer.

El mapa residual magnético es de difícil interpretación, y no presenta una correlación clara con las zonas anómalas gravimétricas.

Las mayores anomalías magnéticas se presentan en las zonas de presencia volcánica, al Sur de los Alcazares, y en los esquistos aflorantes del umbral de Fuente Alamo, en su parte Sur.

La banda débilmente magnética de directriz bética, en la zona Norte de la zona estudiada presenta difícil correlación geológica.

CONCLUSIONES

- Las anomalías de gravedad están relacionadas con los umbrales del substrato.

- Estos umbrales presentan principalmente una orientación NW-SE.

- Aparece otro sistema de umbrales de directriz Bética.

- La situación de las anomalías geotérmicas no parecen relacionarse con la presencia de vulcanismo sino con la presencia de acuíferos carbonatados del substrato en zonas de umbral.

- La potencia sedimentaria de la depresión de Torrepa-
checo puede llegar a alcanzar los 4000 m.

- Las mayores anomalías magnéticas se presentan en una banda entre Los Alcazares y La Palma y sobre el umbral esquis-
toso de Sierra de los Gómez al Sur de Fuente Alamo de Murcia.
