1. INTRODUCCION

1. INTRODUCCION

El presente informe hace referencia a una campaña de gravimetría y magnetometría llevada a cabo por la Sección de Geofísica del IGME en Julio de 1987 en el área de Puebla de la Reina a petición de la Dirección de Minería del anterior. Esta campaña es la prolongación de una similar ejecutada en Octubre de 1986 por la misma Sección de Geofísica. (Ver a este respecto la figura nº 1 donde se aprecia la situación de ambas).

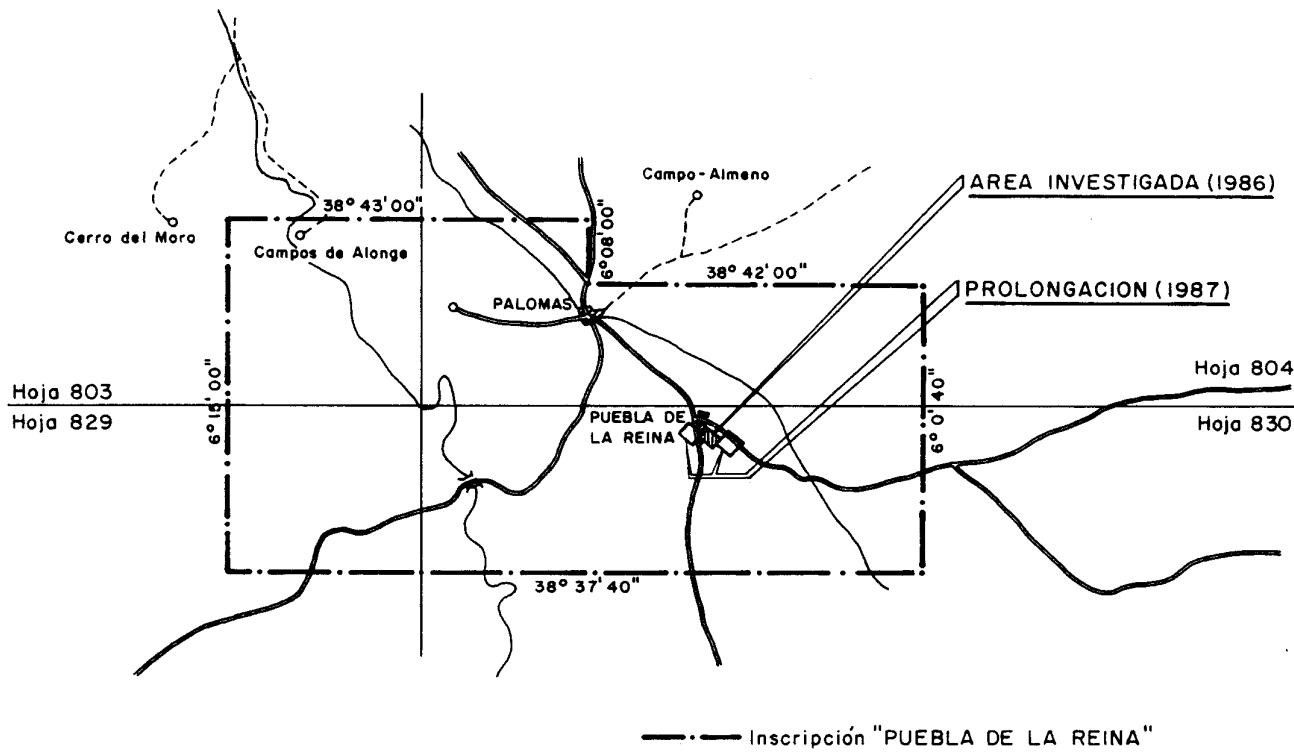

FIG. N° 1.- SITUACION DEL ESTUDIO

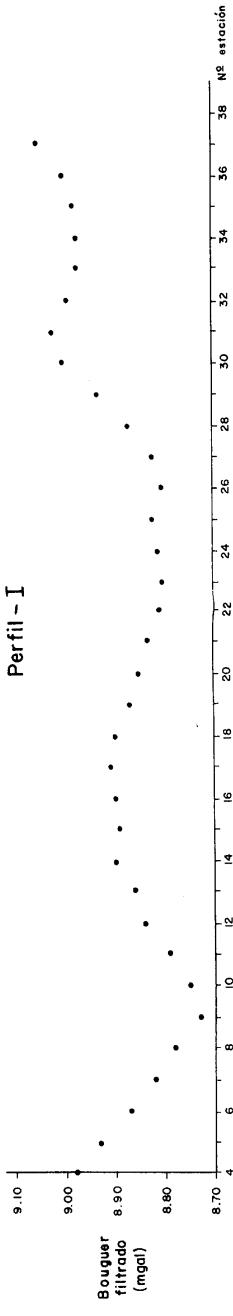

2. ANTECEDENTES

2. ANTECEDENTES

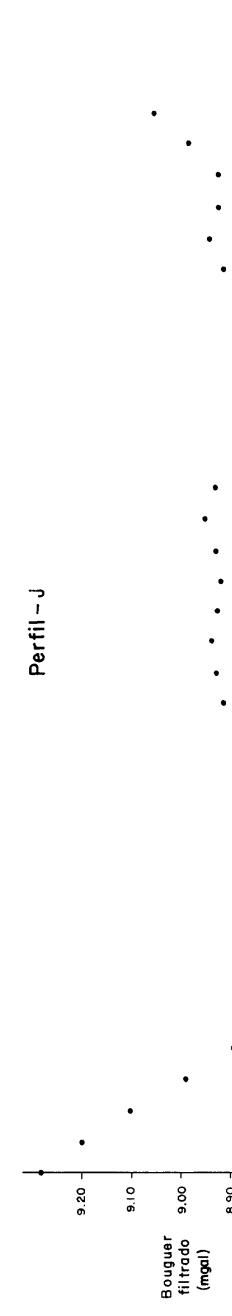

La Dirección de Minería, a través de la oficina del IGME en Peñarroya, viene desarrollando en el área objeto de investigación una serie de trabajos que han puesto de manifiesto la existencia de una mineralización de sulfuros complejos (pirita - calcopirita - blenda - galena). La mineralización encaja en una serie volcano-sedimentaria de carácter intermedio-ácido de probable edad Ordovícica. La cartografía que aparece en el Plano nº 1 es una simplificación de la que figura en el proyecto "Exploración minera en las zonas de Oliva de Mérida y Puebla de la Reina (Badajoz)" (1984). Téngase en cuenta que la cartografía original es bastante interpretativa, por estar la zona muy cubierta y tratarse de una serie muy compleja con numerosas interdigitaciones. La simplificación se ha pretendido realizar de modo que no se pierda información de interés desde el punto de vista gravimétrico y/o magnético. Dicho proyecto comprendió también la realización de varios sondeos mecánicos y una geofísica eléctrica (resistividad y P.I.). El yacimiento, de dirección NW-SE y buzamiento al NE, provoca una anomalía positiva de cargabilidad con valores sensiblemente más elevados que los de la roca de caja, y otra de resistividad con carácter conductor, aunque no muy acusado, lo que se explica porque aquél no es masivo. En los sondeos se han encontrado leyes que llegan al 5.7% Cu, 3.6% Pb y 37.6% Zn. La potencia máxima es de 9 m, con una corrida investigada de unos 200 m que se cierra 50 m al E del indicio y queda abierta al W del mismo pero con leyes que se van empobreciendo en esta dirección. La extensión según el buzamiento, en forma de diseminación, llega a ser de hasta unos 100 m.

Como ya se ha señalado, en Octubre de 1986 la Sección de Geofísica llevó a cabo el trabajo "Estudio gravimétrico y magnetométrico en el sector de Puebla de la Reina (Badajoz)" (clasificado con el nº 40.309 en el fondo documental del IGME) que puso de manifiesto el yacimiento, aunque la anomalía gravimétrica sobre el mismo resultaba bastante débil (entre las estaciones 29 y 32 en el perfil I, la 32 y 34 en el J, y la levísimamente insinuada en las 33 y 34 en el K. Ver la figura nº 2 extraída del informe de 1986). La anomalía positiva más significativa se situaba según el perfil K (estaciones 19 a 28), en coincidencia con anomalías eléctricas detectadas en proyectos anteriores. Este hecho llevó a efectuar la recomendación de realizar un sondeo mecánico sobre la anterior.

3 . OBJETIVOS

3. OBJETIVOS

Con los antecedentes descritos, se pretende extender la campaña de 1986 a fin de tratar de obtener zonas anómalas que puedan corresponder a cuerpos mineralizados como el ya conocido en la actualidad.

4. TRABAJOS REALIZADOS

4. TRABAJOS REALIZADOS

4.1. Duración y equipo de trabajo.

La toma de datos en campo de gravimetría y magnetismo se llevó a cabo del 8 al 28 de Julio de 1987. El equipo es tuvo compuesto por D. José Luis García Lobón, Ingeniero de Minas, D. Julián Coronel Campos y D. Ceferino Avilero Hurtado, Ingenieros Técnicos de Minas, y D. José María Llorente - Delgado, Operador geofísico, todos ellos pertenecientes a la Sección de Geofísica del IGME.

4.2. Instrumentación.

- 1 Gravímetro Worden 553
- 1 Magnetómetro de protones Geometrics G-816 (1 nT de sensibilidad)
- 1 Base registradora Geometrics G-816 (1 nT de sensibilidad)
- 2 Taquímetros Wild T1A

4.3. Perfiles.

Considerando conjuntamente las campañas de 1986 y 1987 se han levantado y medido un total de 33 perfiles, según una dirección N 47° g (centesimales) E (N UTM en el huso 30), separados 100 m con estaciones a 25 m (Ver figura nº 3):

TOTAL 896

Se tiene, pues, una malla conjunta de 1472 puntos; 576 correspondientes a 1986 y 896 en la prolongación de 1987.

4.4. Metrología.

. Topografía

Se ha realizado un levantamiento taquimétrico de cada estación estableciéndose las coordenadas en el sistema UTM.

El equipo utilizado ha sido de 2 topógrafos con 2 peones cada uno que portaban las miras respectivas.

Se declinaron ambos aparatos utilizando la alineación formada por los vértices geodésicos de Puebla de la Reina y Oliva.

Se ha trabajado con dos puntos origen de coordenadas planimétricas XY: el I-30 coincidente con un sondeo mecánico y levantado en la campaña de 1986 y el U-46 al que se dió coordenadas mediante Pothenot visando a los vértices de Puebla de la Reina, Oliva y Vista Alegre.

El vértice de Puebla de la Reina se utilizó también como origen de la coordenada Z.

El levantamiento se ha efectuado sobre itinerarios (según los perfiles) cerrados a no más de 2000 m de perímetro. Se ha compensado cuando el valor de cierre ha estado dentro de la precisión tomada, dada por:

$$C \leq 10 \sqrt{d}$$

c: valor de cierre en cm (altimetría) ó en m (planimetría)
d: longitud del cierre en Km

Los planos números 2 y 3 contienen los esquemas de cierres planimétricos y altimétricos resultantes.

. Gravimetría

Se ejecutaron programas de lectura, de duración siempre inferior a las 2 horas 30 minutos, iniciados y finalizados en la base única del trabajo (Ver el plano nº 1) a la que se le atribuyó un valor de gravedad $g_b = 50.00 \text{ mGal}$.

La gravedad en cada estación se obtiene adicionando al valor de gravedad adjudicado a la base, el incremento medido entre cada estación y dicha base $K \cdot \Delta l$, corregido de efecto lunisolar, CLS y de la deriva del gravímetro, CD:

$$g = g_b + \Delta l \cdot K + CD + CLS$$

siendo K la constante del gravímetro y Δl la diferencia de lecturas entre la estación y la base.

Considerando tanto la campaña de 1986 como la de 1987 se repitieron un total de 167 estaciones, resultando un error cuadrático medio, $Ecm = \sqrt{\frac{\sum d^2}{N}}$, de 6 cmGal. En la expresión anterior, d es la diferencia entre las gravedades determinadas en la primera medición y la repetición y N el número de puntos repetidos. El diagrama de frecuencias obtenido, junto a los valores representativos y la curva de frecuencias relativas acumuladas, aparece en la figura nº 4. En la figura nº 5 se representa la deriva secular del gravímetro W 553 (primera lectura diaria en la base única del trabajo).

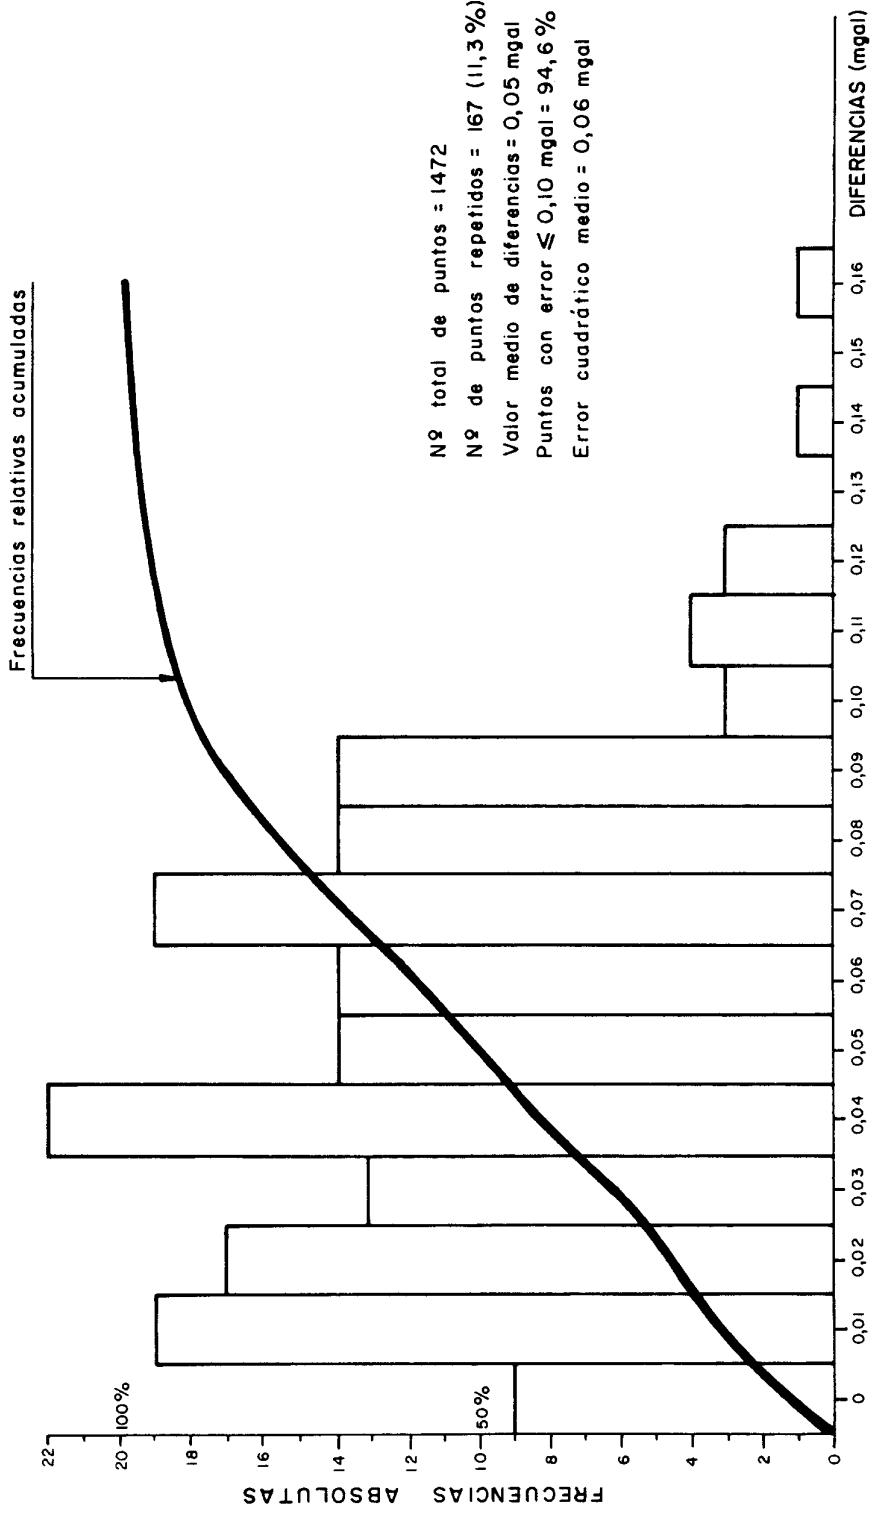

Fig N° 4.- CONTROL DE REPETICIONES DEL GRAVIMETRICO

. Magnetometría

El magnetómetro G-816 proporciona, en cada estación, una lectura absoluta del campo magnético total en la misma. A este valor hay que aplicarle la corrección por variación diurna CVD, determinada mediante registro continuo en punto fijo con la base registradora G-816 A, y la corrección de deriva CD, hallada con los cierres efectuados en los distintos programas en base única (Estaca I-31), obteniéndose una corrección de deriva y variación diurna conjunta con errores aproximados inferiores a 4 nanoteslas (nT) ($1 \text{ nT} = 1 \text{ gamma}$).

El valor del campo en cada estación es, entonces:

$$CG = CG_{\text{medido}} + CVD + CD \quad \text{nT}$$

La repetición de 95 lecturas de control arroja un error de medición $E_{cm} = 10 \text{ nT}$. La consideración tanto de este error como de la intensidad de las anomalías en la zona, nos ha hecho seleccionar para la representación del campo un intervalo de isoanomalas de 50 nT.

Por último, obsérvese que aunque se trata de - lecturas absolutas de campo total, se ha hecho una reducción a base con valor relativo de 43734 nT (valor correspondiente a la estación I-31 según la campaña de 1986).

5. TRATAMIENTO DE DATOS

5. TRATAMIENTO DE DATOS

5.1. Gravimetría

- Gravedad normal g_0 : obtenida por la fórmula del Geodetic Reference System 1967

$g_0 = 978031.85 (1+0.005278895 \operatorname{sen}^2 L + 0.000023462 \operatorname{sen}^4 L) \text{ mGal}$
donde L es la latitud calculada a partir de las coordenadas UTM de cada estación.

- Corrección topográfica T : en cada estación viene dada por la suma de las 3 correcciones siguientes:

- Próxima: zonas B, C y D de Hammer estimada en campo.
- Media: zonas E, F, G, H, I, por interpolación según el método de Neuman aplicado con una malla de corrección de 500 x 500 m y 63 puntos (7 x 9), con origen UTM en X = 751000, Y = 4281500

La malla se encuentra almacenada en el fichero "CTMPUE" (disco flexible de HP-9845).

- Lejana: zonas J, K, L y M por interpolación según el método anterior aplicado en una malla de 4.5 x 4.5 Km y 4 puntos (2 x 2), con origen UTM en X = 751000, Y = 4280500, almacenada en el fichero "CTLPUE".

- . Corrección de altura C_h : engloba la corrección de "aire libre" o de Fayé, C_F , y la de Bouguer, C_B , con los valores siguientes:

$$C_F = 0.30854 \frac{\text{mGal}}{\text{m}} \quad C_B = 0.04192 \frac{\text{mGal} \cdot \text{cm}^3}{\text{m} \cdot \text{g}}$$

con lo que el valor conjunto de la corrección de altura C_h , a densidad de reducción $d = 2.0 \text{ g/cm}^3$, es:

$$C_h = C_F - d \cdot C_B = 0.22470 \text{ mGal/m}$$

- . Anomalia de Bouguer: Se obtiene como diferencia entre la gravedad medida g y la gravedad normal g_0 , afectada por las correcciones de altura y topográfica.

$$A_{2.0} = g - g_0 + C_h \cdot Z + T$$

g = gravedad medida en el punto

g_0 = gravedad normal en el punto

Z = cota del punto

T = corrección topográfica en el punto.

El subíndice 2.0 indica que la anomalía se refiere a esa densidad de reducción, que es a la que corresponden C_h y T . Para otra densidad cualquiera d :

$$A_d = A_{2.0} - \left(\frac{d-2}{2} \right) \cdot C \quad \text{donde } C = 2 \cdot C_B \cdot Z - T$$

La elección de la densidad de reducción "d" para el cálculo de las anomalías de Bouguer se ha efectuado mediante un método estadístico que utiliza los resultados de la misma campaña gravimétrica (el Bouguer a una cierta densidad "d"), en el que el criterio no es, como en otros métodos estadísticos, el de la mínima correlación con la topografía, sino el anular la anomalía gravimétrica allí donde no exista la razón de contraste de densidad para que la haya, con independencia de los accidentes del terreno. El cálculo se efectúa realizando un muestreo de toda la zona de trabajo, en el que cada conjunto de valores de Bouguer (muestra) está definido por las estaciones encerradas en un entorno circular - de radio dado y centro variable. A cada muestra se le trata de ajustar por mínimos cuadrados un plano, de forma que se obtiene la densidad de reducción como un parámetro de cálculo (para cada muestra) que hace mínima la anomalía residual diferencia entre el Bouguer y el plano ajustado. Esta densidad será la de reducción si el conjunto de estaciones de la muestra no define anomalía alguna. La posibilidad de llevar a cabo un muestreo variado hace que se den más situaciones en que no hay anomalía residual que situaciones anómalas, - con lo que un muestreo exhaustivo proporciona un colectivo estadístico del que se puede deducir un valor de densidad de reducción representativo de toda la zona prospectada.

El método que acaba de ser descrito ha conducido a la selección de una densidad de reducción de 2.4 g/cm^3 , densidad que es además ajustada al contexto geológico con el que se trabaja. Por otro lado la zona de estudio es de suave relieve, por lo que la selección de la densidad de reducción no es crítica (ver figura nº 6).

Figura nº 6. (Continuación)

En el plano nº 4 se representan las anomalías de Bouguer a densidad de 2.4 g/cm^3 . El plano incluye las campañas de 1986 y 1987. Es de destacar la consistencia de los resultados de ambas, de forma que no se aprecia discontinuidad o salto alguno entre ellas. Dada la debilidad de las anomalías mineras esperables los valores se presentan sin filtrado alguno.

5.2. Magnetometría.

Para la eliminación de ruidos se ha efectuado un filtro digital pasa-baja de los valores de campo magnético total sobre cada uno de los perfiles de la malla mediante un filtro digital de 7 puntos. En la figura nº 7 aparecen sus coeficientes y su función de transferencia. La figura nº 8 proporciona un ejemplo de un perfil filtrado (el G1). Puede apreciarse que el filtrado es relativamente enérgico, como corresponde a la función de transferencia del filtro utilizado. Obsérvese que al filtrar se pierden las tres estacas de cada extremo de cada perfil.

El plano nº 5 contiene las anomalías de campo magnético total resultantes, incluyendo también la campaña de 1986.

5.3. Ficheros resultantes.

El anexo contiene una copia de los ficheros siguientes:

- Ficheros CTMPUE y CTLPUE , para la corrección topográfica por el método de Neuman.

NUMERO DE PUNTOS= 7 GRADO= 2

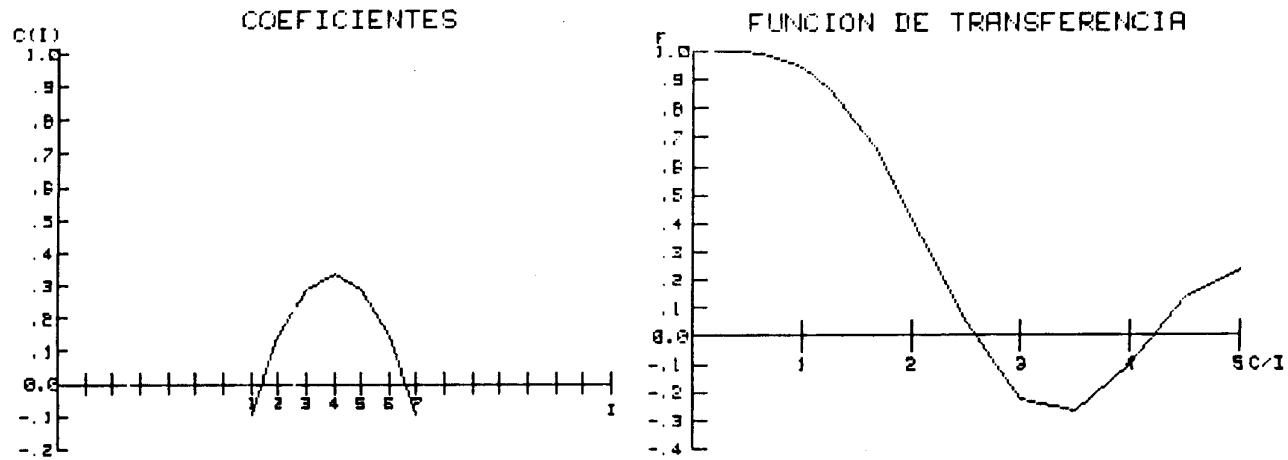

Figura nº 7. Coeficientes y función de transferencia del filtro digital utilizado.

PERFIL G1 SUAVIZADO CON 7 PUNTOS, GRADO 2

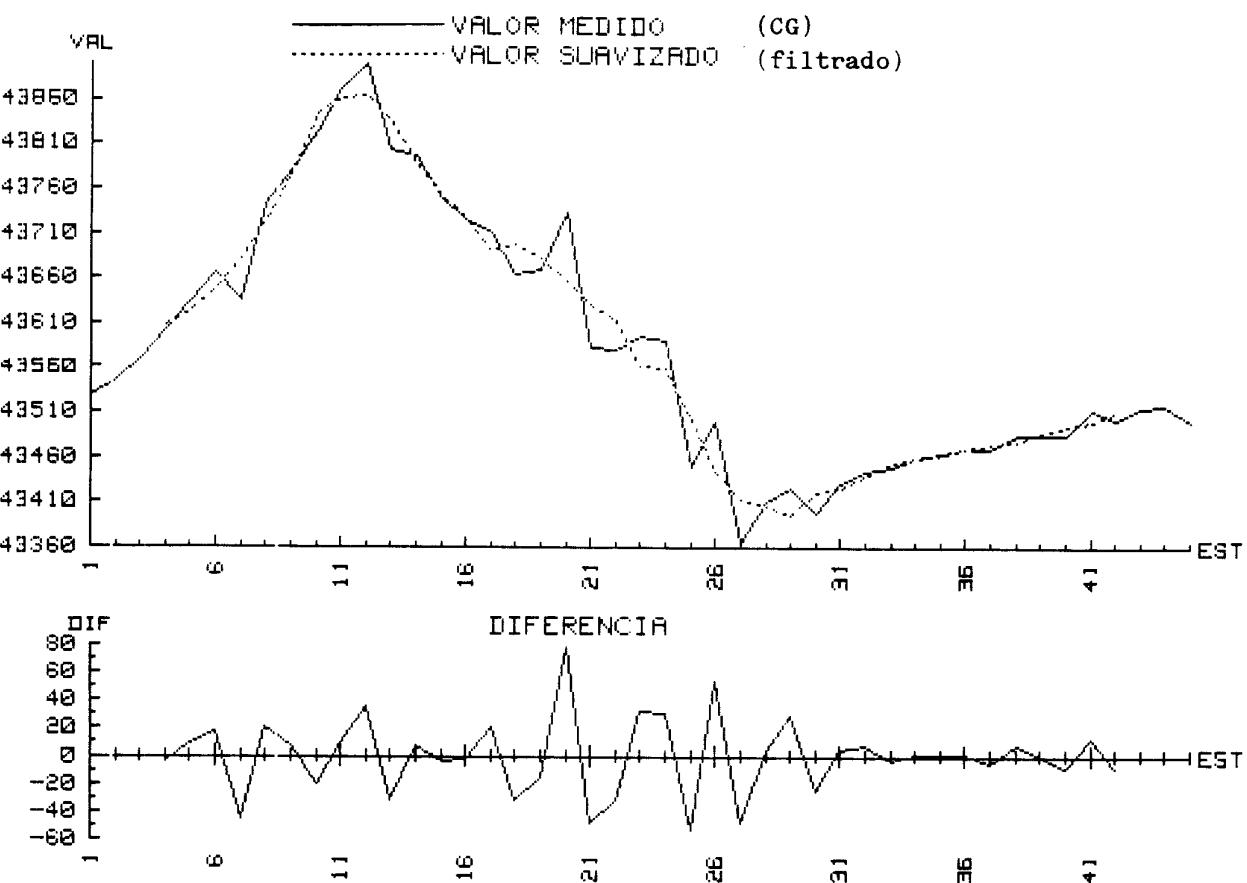

Figura nº 8. Perfil G1 medido y filtrado.

- Fichero GMPR: es el fichero que contiene los datos necesarios para el cálculo de la anomalía de Bouguer (campañas 1986 y 1987). A cada estación (registro) le corresponden las siguientes variables:

- . Np \$: nombre del perfil donde se encuentra.
- . Ne : su nº de orden dentro del perfil.
- . X, Y : sus coordenadas U.T.M. en m.
- . Z : su cota en m.
- . T : su corrección topográfica próxima en cmGal.
- . G, M : los valores de gravedad (mGal) y campo magnético (nT) medidos en la misma, corregidos según lo dicho en el apartado de metrología. A la gravedad medida G se le ha añadido en el cálculo del Bouguer un valor constante de 930.00 mGal, a fin de que las anomalías de Bouguer resulten positivas.

- Fichero GMPRB: contiene los resultados del programa de ordenador que calcula la anomalía de Bouguer. Para cada estación las variables son:

- . Np \$, Np, X, Y, Z, G: las mismas que en GMPR
 - . T: corrección topográfica total en mGal
 - . GN: gravedad normal go en mGal
 - . A y A1: anomalías de Bouguer en mGal a densidades de reducción 2.0 y 2.4 g/cm³ respectivamente.
 - . C: constante de conversión de anomalías según la densidad de reducción.
- Fichero PRMF: las variables de cada registro son aquí Np\$, Ne, X, Y, Z, M, Mf (campo magnético filtrado) y Dif (diferencia entre M y Mf).

6 . INTERPRETACION

6. INTERPRETACION

Empezando con los datos magnéticos y teniendo presente el esquema geológico de la zona investigada, se podrían hacer las siguientes observaciones (Planos nos. 1 y 5):

- Las anomalías magnéticas del plano nº 5 presentan un gradiente general N-S aproximadamente perpendicular a los contactos y estructura E-W del plano nº 1.
- En el plano nº 5 aparecen zonas bien diferenciadas: unas que podríamos denominar "tranquilas", de bajo gradiente, que se relacionarían con los dominios litológicos extensos (v.g. al SE en correspondencia con el anticlinal de rocas detríticas, al NE donde parecen generalizarse las rocas de químismo intermedio - metabasitas en plano nº 1); y otras más atormentadas, en probable conexión con las interdigitaciones de rocas ácidas/intermedias de la serie volcánica de la zona de trabajo, si bien,
- No existe una correspondencia clara entre las alienaciones de rocas ácidas e intermedias del plano nº 1 y las zonas de alto gradiente del plano nº 5. Estas zonas anómalas podrían explicarse - si se piensa en un modelo de placas sucesivas de rocas de distinto químismo ácido - intermedio (interdigitaciones) cuyo contacto daría lugar a las anomalías, lo que llevaría a corregir la cartografía del plano nº 5 si se desprecian otros efectos.

tos (derivados de variaciones de potencia en profundidad y/o del juego de las fallas que se insinúan en el plano nº 5).

- Como era de esperar la mineralización no se refleja en el mapa magnético (los sulfuros complejos, salvo si existe pirrotita en cantidades apreciables, no producen anomalías magnéticas). Tampoco parece existir marcador magnético alguno que pueda controlar el yacimiento.

En cuanto a los datos gravimétricos (Plano nº 4):

- Zona investigada en 1986 (perfils A al O): observe que en relación con los planos gravimétricos del informe "Estudio gravimétrico y magnetométrico en el sector de Puebla de la Reina (1986)" el plano nº 4 presenta las anomalías de Bouguer sin filtrar. Aparecen en él 3 anomalías positivas relevantes: la del perfil G (estaciones 19 - 20), la que corresponde a la mineralización (estaciones 30 y 31 de los perfils H e I) y la del perfil K (estaciones 20 a 29).
- En la prolongación de 1987 son anomalías positivas importantes la situada entre los perfils B1 y A (estaciones 20 - 21), la de los perfils S y T (estaciones 56 - 58) y la del perfil W (estaciones 59 - 60).
- Estas anomalías se corresponden ya con anomalías magnéticas positivas (perfil G), ya con negativas (perfils A y W).

- Todas las anomalías citadas, salvo la del perfil K, se sitúan sobre rocas de quimismo intermedio (metabasitas según la denominación del plano nº 1. Sin embargo también existe alguna anomalía negativa sobre rocas de este tipo -perfil M, estaciones 21 a 23-).
- En general el plano ofrece un aspecto ruidoso, con numerosas inflexiones en las curvas debido al juego contacto/falla, lo que constituye un carácter gravimétrico típico de las series volcano-sedimentarias. Si se prolongara la falla del plano nº 1 al W del perfil D tal como se observa en el plano nº 4 (línea a trazos), quedaría un dominio al N de la línea falla-prolongación en el que los gradientes son acusados y no se observan mínimos importantes, lo que se interpretaría como un predominio de las rocas más densas (metabasitas) al N de dicha línea. Esto se ve confirmado por ciertos rasgos del mapa magnético (zona de tranquilidad al N). Parece ser pues que en su conjunto todo el área se podría interpretar en términos de las tres zonas siguientes: la primera al N de la discontinuidad principal con preponderancia de rocas de quimismo intermedio (alto gradiente y ausencia de mínimos en gravimetría, suavización - del gradiente magnético), la segunda la zona del anticlinal del SE (plano nº 1), y la tercera situada entre ambas comprendería las anomalías gravimétricas y magnéticas significativas en relación tanto con la discontinuidad principal (y otras secundarias) como con las interdigitacio-

nes de rocas ácidas/intermedias.

- Todo este contexto produce un efecto oscurecedor sobre posibles fuentes de anomalía de carácter mineral. (Ver el apartado de interpretación del informe de 1986). Este efecto adquiere gran relevancia cuando en ensayos realizados para separar anomalías gravimétricas regionales y residuales (los datos gravimétricos fueron sometidos al siguiente proceso: giro de la malla, interpolación en malla cuadrada, filtrado digital bidimensional y separación de anomalías. Las anomalías residuales significativas son las que aparecen con el símbolo \oplus ó \ominus en el plano nº 4), éstas son siempre inferiores a las 20 cmGal. Es por ello que resulta muy arriesgado señalar como de especial interés alguna de las anomalías citadas en este apartado.

Madrid, Diciembre 1987

Nº TOTAL DE ESTACIONES PROCESADAS 1472

El nombre del fichero creado es: GMPRB; contiene 1472 registros de 88 bytes.
Está grabado en la unidad: :H7,0,0

Contiene las siguientes variables:

Nº de perfil, Nº de estación, Coordenada X, Coordenada Y, Coordenada Z,
Gravedad medida, Gravedad normal, Corrección topográfica total,
Anomalía de Bouguer a densidad 2., Factor de conversión, Anomalía de Bouguer
a densidad 2.40.
