## O.- RESUMEN Y CONCLUSIONES.

Se han medido 448 estaciones de gravimetría, separadas unos 500 m., con el objeto de complementar unas mediciones efectuadas en 1973. Los valores están unidos a la R.G.F. de 1960 y efectuadas todas las correcciones que implica el sistema.

Para el tratamiento de datos, estas nuevas estaciones se han unido a las antiguas, disponiendo en total de 1016 mediciones, de las que se ha interpolado gráficamente una malla de 500 m. de paso.

Estos valores se han procesado primeramente para filtrar las frecuencias superiores a 0.25 c/i y posteriormente se ha calculado la continuación de campo a 2 pasos de malla, considerada como regional, su consiguiente residual así como la primera y segunda derivadas verticales. Todos estos valores se han transportado por plotter, dibujando los mapas de isovalores, así como los perfiles, sobre los que se ha fundamentado la interpretación.

El tratamiento digital seguido lleva consigo una pérdida de una zona de borde de 3 a 4 Km, ya tomada en cuenta en la toma de datos en campo.

Posteriormente se ha analizado la información sísmica, eléctrica, magnética, mapa de Bouguer, residual y deri-

vadas, obteniendo un único plano de interpretación, donde quedan reflejadas las principales fallas y discontinuidades.

En conclusión, la depresión del Vallés en su parte nortoriental está limitada al norte por una falla y al sur por un sistema escalonado que sitúa la parte más hundida al Sur-Oeste de la Garriga. De Oeste a Este existen también zonas de diferente hundimiento, limitadas por un sistema fallas ortogonal al anterior

Es digno de mención que las fallas detectadas por el magnetometro se acusan con mínimos de susceptibilidad magnética.

## INFORME - FASE PRELIMINAR DE PROSPECCION DE LOS RECURSOS GEOTERMICOS DEL VALLES (BARCELONA).

### 1.- OBJETO DE LA CAMPAÑA. ANTECEDENTES.

Este trabajo pertenece a la fase preliminar de prospección de los recursos geotérmicos del Vallés (Barcelona).

En los trabajos realizados por la Compañía General de Sondeos y en particular en un estudio por el método de S.E.V., se vió la existencia de una discontinuidad en la cuenca del Vallés, al Sur de la línea La Garriga-Caldas de Mombuy, así como un sistema de pequeñas fallas, ortogonal al anterior.

El mejor conocimiento de la estructura de la parte oriental de la depresión del Vallés, y especialmente de la zona antes aludida, es el objeto de esta campaña gravimétrica.

Se dispone de los siguientes documentos:

- Gravimetría 1/50.000, realizada por el IGME en esta región en 1973 (autorizada su utilización por APEX).
- Geología 1/25.000 y 1/10.000, realizada por la Compañía General de Sondeos en 1976.
- Perfiles sísmicos realizados en 1974, por la Compañía - General Geofísica (autorizada su utilización por APEX).
- Prospección eléctrica realizada por Cia.General de Sondeos en 1977.

## 2.- SISTEMA DE TRABAJO ELEGIDO.

La gravimetría de 1973 resulta insuficiente para la resolución del problema planteado, por varias razones: la estructura de la depresión no queda definida, al no disponer de valores exteriores a la misma; la densidad de mediciones en la zona Caldas-La Garriga es insuficiente; y finalmente, se hace necesario disponer de unos valores "de borde", en razón del tratamiento que se va a aplicar a la mediciones: filtros digitales, continuación y derivación de campos.

Se ha procedido pues, a una ampliación y complementación del trabajo de 1973.

En el plano nº 1 se indican los itinerarios antiguos y los nuevos, así como la zona propiamente a estudiar y la de "borde", estando ésta lógicamente con menos densidad de medidas.

### 3.- MEDICIONES Y CALCULOS DEL BOUGUER.

#### 3.1.- Equipo de trabajo.

Del 16 de mayo al 30 de junio de 1977, se ha -  
desplazado un equipo a Mataró, donde se instaló una ofi-  
cina de calculo.

Participaron en este equipo:

Jefe de Equipo: D.Juan L.Plata Torres  
Dr.Ingeniero de Minas  
Topografía: D.Julian Coronel  
Perito de Minas  
Gravimetría: D.Ceferino Avilero  
Facultativo de Minas  
D.Luis Paniagua  
Auxiliar Administrativo  
Un mecánico y 4 peones

Participó además en los cálculos el Ingeniero de Minas,  
D.Miguel Rodriguez González.

Se utilizó el gravimétero Worden 553, calibrado en las -  
bases de Fraga el día 8-6-77, de constante  $K=0.10276$  y  
el magnetómetro de protones Geometrics 816.

La topografía se realizó con taquímetros Wild T1-A.

Para los cálculos de topografía y gravimetría se emplearon en oficina máquinas HP-67 con programas propiedad del IGME.

### 3.2.- Topografía.

Se han levantado un total de 448 estaciones, a 500 m.

Dada la necesidad de disponer de las coordenadas y cotas al día, a fin de poder calcular los valores de anomalías, se ha seguido el sistema de compensar los itinerarios - por cierres en vértice a N.A.P., esperando a disponer de un polígono cerrado solo en caso de no existir las señas topográficas anteriores.

Los tramos en antena se han cerrado por itinerarios de ida y vuelta, apoyándose en algún caso en puntos existentes del trabajo de 1973.

En los planos 2 y 3 se indican los errores de cierres, - aceptados con el criterio e  $10 K$  ( $K$  longitud del itinerario en Km, e en m. para planimetría y cm. para altimetría).

Se ha empleado el sistema de coordenadas Lambert.

### 3.3.- Gravimetría.

#### 3.3.1. Bases.

En el plano 1 se indica la red de bases y en el croquis adjunto sus cierres. La de partida ha si-

(desviación típica = 5)

Error Medio estimado en C.T. próxima (B-C-D) = 15%  
 " " " largo (J á M) = 10%

do la base 14 (de Sabadell) perteneciente al trabajo de 1973, con un valor absoluto de 980248.18 mGal (se han sustraído 979.000, adjudicandole 1248.18 mGal, para manejo de menor nº de cifras).

Esta base está unida a la Red Gravimétrica Fundamental - del I.G.C. de 1960 (Elipsoide de 1930, de Hayford).

Se adjunta los croquis y descripciones para localización futura de las nuevas bases.

### 3.3.2. Control del gravímetro.

Se estableció un punto fijo, donde se efectuaron lecturas al principio y final de cada jornada de medición, con el objeto de controlar la deriva del gravímetro. Estas se representan en el gráfico adjunto, corregidas de variación L-S. La deriva media secular fué de 14 cmGal/día y la de trabajo de 4 cmGal/h.

Las mediciones del día 21 fueron repetidas en programas posteriores.

### 3.3.3. Control de las lecturas.

A fin de determinar la calidad de las lecturas del gravímetro se han repetido un 10% de las medidas, en programas independientes. La distribución de errores se muestra en el gráfico adjunto, siendo el error medio de  $\pm 2$  cmGal.

### 3.3.4. Correcciones.

a) Deriva: se ha hecho por interpolación lineal de los valores medidos en base, con programas de 120 minutos.

b) Luni-solar: empleando las tablas publicadas por la E.A.E.G.

c) corrección topográfica (método de Hammer)

- próxima (B-C-D) a la estima en campo .  
Error normal del 15%.

- media (E a I): en plano 1/50.000. Error calculado por repetición de 50 correcciones: 10%.

- larga (J a M): por interpolación según el método de Neuman, sobre malla de 5000 m. en plano 1/200.000. Error normal de 10%.

Según puede verse en los listados adjuntos de valores, la C.T. total llega a ser bastante elevada en algunos itinerarios.

El error total, de la C.T., produce un ruido en el plano de Bouguer, que junto con otras consideraciones que haremos más adelante, justifica el filtrado de los valores.

d) corrección por latitud, aire libre y bouguer.

Según el método habitual, para densi-

dad 2.0. Mediante el factor de conversión C, se han obtenido los valores en densidad 2.4, ya que fué esta la adoptada en 1973.

$$A_{2.4} = A_{2.0} - \left( \frac{d-2}{2} \right) C$$

En el listado de valores quedan registrados:

E : Estación

X, Y, Z: coordenadas Lambert y cota absoluta en metros

G : gravedad medida

GN: gravedad normal sobre el geoide

T : corrección topográfica total

A : anomalía en densidad 2.0

C : factor de conversión

AL: anomalía en densidad 2.4

Todos los valores gravimétricos están indicados en cmGal.

### 3.3.5. Empalme con los valores antiguos.

En el transcurso de las mediciones, se han encontrado señales de estaciones realizadas en 1973. Vueltas a medir con el gravímetro, se han encontrado unas diferencias entre 3 y 11 cmGal, lo que da una gran confianza al empalme de la red de bases y hace las medidas perfectamente comparables.

Sin embargo, calculada la anomalía de Bouguer para estos puntos y otros se han situado muy próximos a puntos antiguos, se han encontrado unas diferencias importantes y coincidentes en orden de magnitud con la corrección topográfica larga para esas estaciones. Revisando los cálculos de 1973, hemos encontrado que, en efecto, no fué tomada en cuenta dicha corrección. Esto produce evidentemente un "ruido" indeseable en el empalme de los valores antiguos con los nuevos. Al trazar el Bouguer con equidistancia de 1 mGal, no hay sin embargo una distorsión de los cursos que imposibilite el empalme. No obstante esta circunstancia se tendrá en cuenta en el momento de elegir el filtro de valores.

### 3.4.- Plano de Bouguer y perfiles por interpolación.

En la oficina de campo se dibujó un Bouguer de las nuevas mediciones, para comprobar su correcta ejecución y evitar la incompleta medición de posibles anomalías. Estas 448 estaciones se han unido con 568 de las antiguas que son, según la numeración del Mapa Gravimétrico Nacional 1/50.000 que confeccionó el I.G.M.E:

Hoja 364 : completa

Hoja 393       "

Hoja 421       "

Hoja 420: de 155 a 178 y 193 a 208

Hoja 392: 34 a 61: 144 a 150: 189 a 202; 216 a 353;  
359 a 365.

Por esta razón la numeración de estaciones aparece con varias repeticiones. El conjunto de las 1016 estaciones se ha transportado por Plotter y se ha vuelto a dibujar un único Bouguer para toda la zona.

Para proseguir con el tratamiento de datos, es necesario disponer de estos en malla; para ello se ha elegido el sistema de trazar perfiles distanciados 500 m., por corte con las curvas isoanomalás. En estos perfiles se han interpolado de nuevo valores cada 500 m. Estos valores son los que realmente nos sirven de punto de partida para los cálculos a efectuar. Se han sumado 22 mGal a todos los valores por la mayor facilidad de emplear números positivos.

Suponen en total 54 perfiles, con 44 estaciones por perfil cuya situación se indica en el plano de Bouguer.

#### 4.- TRATAMIENTO DE DATOS.

En el organigrama adjunto puede seguirse las diversas etapas hasta la obtención de los planos de interpretación.

##### 4.1.- Filtro digital bidimensional.

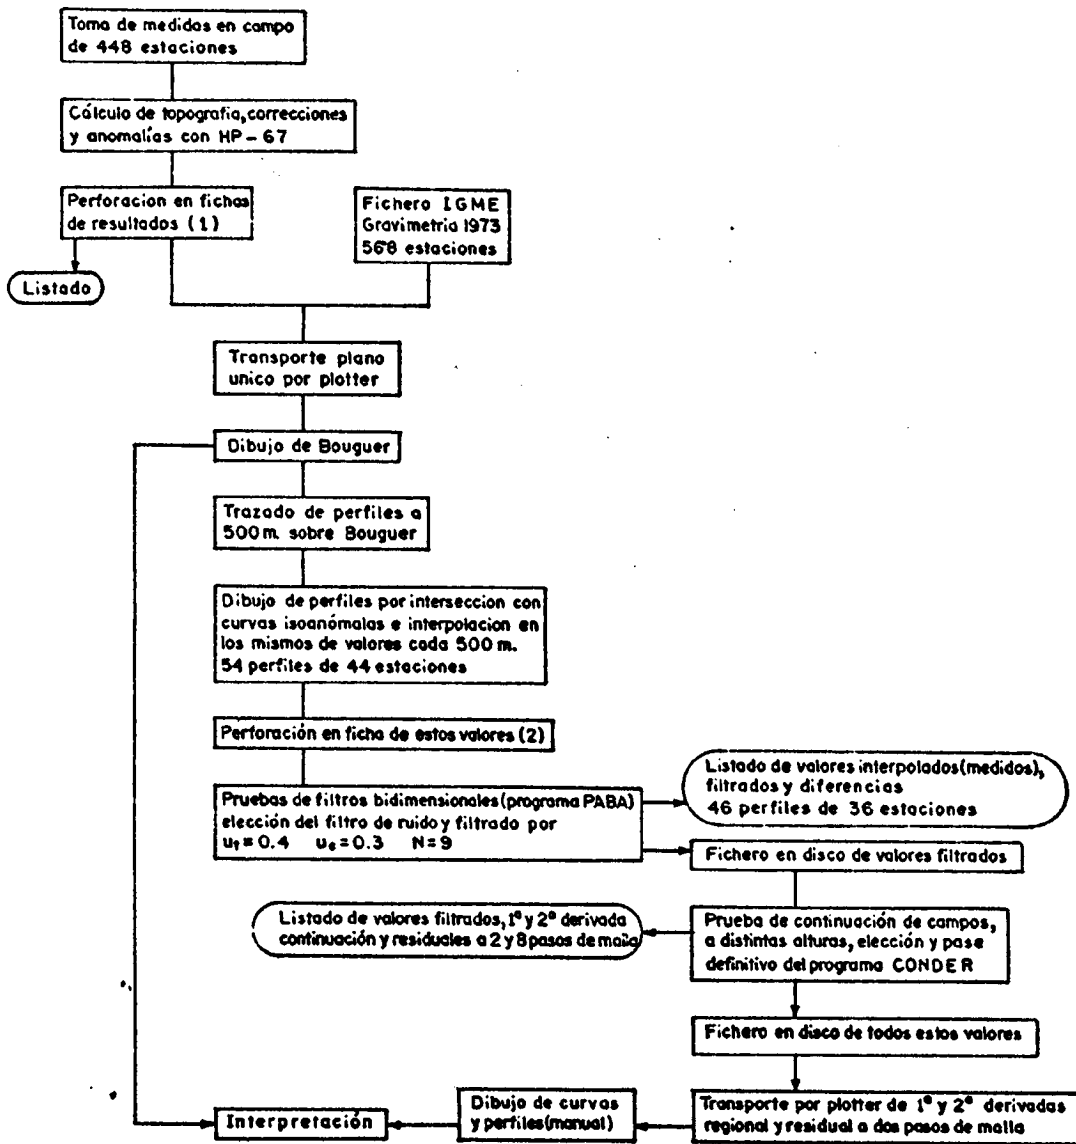

El objeto de aplicar este filtrado es eliminar el ruido de los datos (ruido procedente de las medidas, - corrección topográfica y empalme de valores antiguos y - nuevos) y suprimir las altas frecuencias, requisito indispensable para obtener posteriormente la primera y segunda derivadas.

Con este objeto, hemos probado previamente varias frecuencias de terminación ( $U_t$ ) y de corte ( $U_c$ ), cuyas funciones de transferencia, valores filtrados y ruido suprimido se representan en los gráficos adjuntos.

Hemos elegido  $U_t=0,4/c/i$   $U_c=0.3 c/i$  puesto que como puede verse en la F.T., elimina por completo las anomalías de una amplitud inferior a 1200 m (0.4 c/i) y reduce a menos del 70% las anomalías de longitudes inferiores a 2000 m. ---- (0.25 c/i).

La matriz de coeficientes del filtro se ha elegido de 9 x 9 ya que de esta forma solo se pierden cuatro perfiles en cada extremo y 4 estaciones al principio y fin de cada perfil.

La malla resultante es pues de 46 perfiles con 36 estaciones.

(1) Formato { NE, X, Y, Z, G, GN, T, A, C, A1  
I3, 2F8.0, F5.2, F9.2, F8.2, F4.2, F7.2, F6.2, F7.2

(2) Formato 14X, 22F3.1

**ORGANIGRAMA DE TRATAMIENTO DE DATOS DE GRAVIMETRIA**

**MATARO 1.977**

En el listado resultado de este filtro, los valores "medidos" se refieren a los interpolados. El perfil P-1, estación E-1, se corresponde con el primitivo P-5, E-5. En lo sucesivo solo se empleará esta nueva nomenclatura.

Dado que la amplitud del ruido filtrado no supera en general los 0.40 mGal, no consideramos necesario dibujar un nuevo Bouguer, al estar este con equidistancias de 1 mGal.

La comparación entre las curvas originalmente trazadas, las que resultarían de trazarlas con los valores interpolados y el resultado del filtro, pueden apreciarse en el ejemplo que hemos elegido y representado en el gráfico adjunto.

#### 4.2.- Derivación y continuación de campos.

Suprimido el ruido, la obtención de la derivada vertical primera y segunda, tiene por objeto resaltar las anomalías presentes.

Con la continuación de campos hacia arriba, lo que se pretende es obtener una representación de la superficie regional.

Para ello se ha probado inicialmente con 1,2,4 y 8 pasos de malla, resultado que se visualiza en el ejemplo adjunto.

Según el mapa de Bouguer Nacional 1/1.000.000 editado por el I.G.C., el gradiente normal, de origen profundo, en esta zona es del orden de 2 mGal/Km, en la dirección elegida para los perfiles y buzamiento NW, pasando a 1 mGal/Km a partir de la línea central de nuestra zona. Además es ya conocido el tipo de anomalía gravimétrica que produce una depresión sedimentaria, por lo que nos interesa incluir esta en la regional, ya que nuestro interés está centrado en las estructuras interiores de la cuenca y no en ella misma.

Por estas razones, tras las pruebas de continuación, hemos optado por elegir la de 1.000 m. como más representativa de una regional, siendo su diferencia con los valores medidos una estimación cualitativa de la residual.

Debido al método matemático empleado en el cálculo de las derivadas y continuación de campos (solución de la ecuación de Laplace por desarrollo de Fourier bidimensional) se pierden unos 2 Km en cada extremo de los perfiles.

En los listados de este programa se incluye no obstante la regional y residual de 8 pasos de malla. Los valores de 2ª derivada deben multiplicarse por 10 para obtenerlos en unidades de  $\text{mGal/Km}^2$ .

En el ejemplo adjunto puede apreciarse el tipo de información suministrado por la derivación. La 2ª derivada es más sensible a la reparación de todo tipo de integración de anomalías. La primera derivada permite deducir la dirección del buzamiento de las fallas, aunque integra en una misma variación de gradiente el efecto de varias estructuras.

## 5.- INTERPRETACION.

### 5.1.- Información suministrada por la sísmica.

La estructura definida por los perfiles sísmicos S-2, S-3 y S-5 es perfectamente coincidente con la reflejada por el Bouguer. Esto puede apreciarse comparando el primer horizonte de reflexión, suministrado por C.G.S. y los valores residuales de gravedad.

Quiere esto decir, que por lo menos en esta zona, el Bouguer (o su residual) representa las variaciones topográficas del fondo de la cuenca, dando la sísmica su imagen cuantitativa.

Así pues, en las que nos ocupa (de Sentmenat-La Garriga) la parte más elevada de la cuenca se encuentra bajo Lissa de Vall con unos 500 m. de recubrimiento; esta elevación se va hundiendo hacia Sabadell, de forma lenta, hasta alcanzar los 2000 m. Hacia Caldas de Mombuy el hundimiento reflejado por la sísmica es menor, alcanzando solo 1200 m. por lo que es evidente que en esta zona la situación del Bouguer no obedece tan solo a cambios topográficos del subsuelo, si no a contrastes laterales de densidad que acentúan la gran anomalía mínima entre Caldas y La Garriga Tendríamos que concluir que por tanto, la zona un mayor espesor de recubrimiento es la de Sabadell.

# PERFILES SISMICOS

### 5.2.- Información suministrada por los S.E.V.

La campaña realizada por C.G.S. representada en forma de isobatas del resistivo, podemos dividirla en las siguientes indicaciones:

- El hundimiento más rapido se localiza al Sur-este del - Caldas.
- Entre Caldas y Sentmenat la pendiente es menor y además casi ortogonal a la anterior.
- Entre Santa Eulalia y La Atmella la pendiente es aun menor pareciendo indicar la existencia de una elevación en tre dos zonas más hundidas al este y oeste.
- Nuevamente una fuerte pendiente al Sur de La Garriga.

En líneas generales, la coincidencia con el Bouguer vuelve a ser muy buena; esto nos situaría el espesor de recubrimiento en la fosa de Caldas=La Garriga con un máximo al Sur de La Garriga y otro al Sur de Caldas.

### 5.3.- Información suministrada por los perfiles magnetométricos.

Estos perfiles fueron realizados durante la campaña gravimétrica de junio de 1977 con un magnetometro de protones. Dada la densidad de población e industrias de la zona, solo fué posible realizar dos itinerarios y uno de ellos incompleto por imposibilidad de efectuar las mediciones. Se trata por tanto de unos datos muy aislados y que hay que analizar con las consiguientes reservas.

# ITINERARIO 1 DE MAGNETOMETRIA

# ITINERARIO 2 DE MAGNETOMETRIA

El perfil 1 está trazado entre Caldas y Santa Eulalia, -  
atravesando el mínimo gravimétrico hasta internarse en el  
triásico. Al sur del perfil hay un mínimo interpretable -  
como una falla de lado hundido al norte. Su situación es  
próxima a la indicada (no muy claramente) por el perfil -  
sísmico 3, por lo que, aunque ninguna de las dos indica -  
ciones sea muy buena, ante la coincidencia, las hemos te -  
nido en cuenta.

En este mismo itinerario, pasada la cuenca sedimentaria -  
se marca otro mínimo: falla de hundimiento norte, esta -  
vez confirmada por la cartografía conocida.

Respecto al itinerario 2, es de destacar la diferente in -  
tensidad de campo al norte y sur de Granollers. La parte  
norte se inicia de nuevo con una probable indicación de -  
falla, presenta un mínimo sin explicación evidente a la -  
altura de las estaciones 118 a 120 y marca claramente la  
falla norte, esta vez un lado hundido al sur.

#### 5.4.- Análisis del mapa Bouguer.

El borde norte refleja los cambios de facies y  
topografía sin que para nosotros tenga más interés, ya que  
solo se ha medido a efectos de tomar una banda en exceso -  
para posibilitar los cálculos de filtros y derivadas. Uni -  
camente dejaremos constancia de que el norte de la falla -  
Caldas-La Garriga, el Bouguer tiene un caracter totalmente  
distinto del resto del plano y su interpretación se adapta  
ría mejor a otro tipo de consideraciones de las que aquí -  
vamos a emplear.

A todo lo largo de la curva de -15 mGal, se refleja perfectamente el gradiente elevado motivado por la falla que limita al norte de la depresión del Vallés.

La curva de 0 mGal limita al borde sur, donde el gradiente pasa de ser del orden de 2 mGal/Km, hasta 5 mGal/Km más al norte.

Este fuerte gradiente delimita bien el contacto granítico-Mioceno.

La depresión entre estas dos discontinuidades presenta una serie de "bloques" a distinta profundidad. En general, la mitad norte está más hundida que la sur y ambas separadas por una falla longitudinal que será mejor definida en los perfiles de primera derivada. Estos bloques están señalados en el Bouguer por las variaciones de gradiente y por la discontinuidad de la zona de mínimo.

5.5.- Análisis de las derivadas.

Hemos dibujado para todos los perfiles los valores de derivación. Aquí solo incluimos los más representativos.

Partiendo de todos los perfiles hemos situado los límites de zonas de discontinuidad que se aprecian con mayor claridad.

La situación de los puntos de inflexión es incierta, por lo que la localización de los bordes de falla no resulta con mayor precisión que  $\pm$  500 m, que es el paso de malla elegido. Por otra parte, no debe olvidarse que la gravimetría solo pone de manifiesto fallas con contraste de densidad -

entre ambos bordes.

La primera derivada permite definir en la mayoría de los - casos de qué lado queda la parte más hundida o menos densa.

La segunda derivada resuelve mejor los casos en que se tra- ta de más de una estructura responsable de la misma anoma - lía.

La representación en planta de las curvas isovalores de - primera y segunda derivada ha permitido establecer mejor el seguimiento perfil a perfil de las distintas anomalías.

5.6.- Plano de interpretación.

Analizados todos los datos de los párrafos prece - dentes, y teniendo en consideración únicamente las anoma - lías mejor definidos por todos ellos se ha dibujado un pla - no de interpretación en el que se señalan las fallas con - su buzamiento, en los casos determinables, así como los - principales ejes de estructuras o líneas de discontinuidad (trazado a rayas).

Los términos "elevación" y "hundimiento" son relativos. El plano residual permite apreciar mejor cuales son las zo - nas más o menos elevadas.

Madrid, 7 de noviembre 1977
